Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

**Description**

[0001] The present invention relates generally to antennas and, more particularly, to motor vehicle antenna constructions in the form of slot antennas.

[0002] A number of antennas has been developed to replace typical monopole antennas which are still widely used in motor vehicles because of their simple structure and effectiveness. However, because such antennas protrude from exterior surfaces of the vehicle, they are exposed to destructive impacts and create aerodynamic disturbances that affect performance or create noise as the vehicle travels. Moreover, retractor mechanisms for such antennas substantially increase the cost of supplying the component, and they displace the monopole from an operable, exposed position to an inoperative, retracted position where reception is obstructed by adjacent conductive parts such as engine parts, chassis parts or body panels.

[0003] One previous way to overcome such problems has been to incorporate the antenna in other body panels. For example, conductive body panels such as expanded areas of sheet metal may be employed to form slot antennas by cutting a slot into an expanded ground plane made of conductive material. Sheet metal panels of the vehicle have previously been employed to form the slot antenna. Conductor terminals are secured at locations on opposite sides of the slot to transfer the voltage signal received by the antenna. Adjusting the relative positions of the terminals on the ground plane affects the impedance of the antenna, but the ground plane is generally very large in relation to the size of the slots. Moreover, the surface area of ground plane would typically be enlarged in order to enhance the performance of the antenna. A shield of a coaxial cable may be attached to one side of the slot and the centre conductor of the coaxial cable secured to the opposite side of the slot, the impedance being adjusted by moving the feed point along the length of the slot and adjusting the dimensions of the slot itself. Typically, a slot would be a half wavelength long. For example, a slot in the ground plane would be 18.75 inches long for reception of a signal at 315 megahertz.

[0004] Moreover, the directional sensitivity of the antenna is affected by the alignment of the antenna, and horizontal panels of the motor vehicles are not most advantageous for reception of higher frequency signals, for example on the order of a 315 megahertz signal used for remote keyless entry systems, or a 820-895 megahertz signal used for cellular phone systems. For example, U.S. Patent No. 5,177,494 to Dorry et al. discloses a slot antenna arrangement in which a plurality of antennas are arranged in numerous orientations throughout the vehicle, thus substantially increasing the complexity and cost of the slot antenna system. Moreover, a ground plane aligned at a proper angle, for example a side panel or window area of the vehicle, would require a substantial surface area to be covered with a conduc-

tive material and thus tend to obscure visibility and interfere with operation of the vehicle.

[0005] Other known types of antennas have been adapted for use in the window area of motor vehicles.

5 For example, it has been known to use the heater grid which extends across a large portion of the rear window as an AM radio signal antenna. However, such an antenna does not perform well in the FM radio frequency range and higher ranges. Accordingly, an additional antenna for reception of FM radio signals has been mounted to windows where the heated grid has been combined with developed filter circuits for reception of AM radio signals. For example, the FM antenna may be an extended conductor arranged in a zig-zag pattern 10 across a substantial length of the rear window of the vehicle. As a result, there is very little window space left in a vehicle rear window carrying these known types of antennas for installation of additional antennas that could receive higher frequency radio signals, for example, radio signals used for remote keyless entry systems and cellular telephone systems, that would require large areas when constructed according to known techniques.

15 [0006] According to the present invention, there is provided a slot antenna having a slot in a reduced ground plane for a motor vehicle insulating panel comprising a conductive strip or tape narrow in relation to the width of the slot, formed in a loop on the insulating panel, said loop forming the slot having a length corresponding to a fraction of a predetermined wavelength, 20 said reduced ground plane consisting of said strip formed in a loop peripherally defining the slot, wherein said fraction is smaller than the half wavelength of an expanded ground plane slot antenna, said loop is of rectangular form and wherein non-common conductor terminals are aligned across the slot on its length sides.

25 [0007] As with previous slot antennas, the impedance of an antenna embodying the invention may be matched with the impedance of the transmission by adjusting the position of the terminals of the conductors, for example, the centre conductor and shield of a coaxial cable, on the conductive strip loop. Moreover, the reduced length of the antenna compared to previously known slot antennas, and the reduced dimension of the conductive strip provide substantially less obstruction to visibility 30 than previously known antenna constructions. As a result, it is an advantage of the present invention that slot antennas of the type constructed according to the present invention can be used in conjunction with other window antennas such as heater grid and FM pattern

35 antennas which may be mounted in a single window panel.

40 [0008] As a result, it will be understood that the present invention provides substantial advantages over previously known slot antennas. The present invention provides an advantageous glass mounted antenna for use with cellular telephone systems or remote keyless entry systems.

45 Moreover, the conductive material ground plane occu-

pies substantially less surface area than previously known slot antennas, so that the antenna does not obscure visibility over a large surface area. In addition, the present invention provides an advantageous antenna construction which provides improved gain by stacking a plurality of loops formed from conductive strips in accordance with the present invention. Furthermore, the present invention provides an advantageous window antenna structure including a multiple antenna construction in a single window panel.

[0009] The invention will now be described, by way of example, with reference to the accompanying drawings, in which:

Figure 1 is a perspective view of a motor vehicle employing multiple antennas in a single window panel according to the present invention;

Figure 2 is an enlarged plan view of one of the antenna structures shown in Figure 1;

Figure 3 is an enlarged plan view of another antenna construction shown in Figure 1 according to the present invention;

Figure 4 is a graphical representation of the performance of an antenna shown in Figure 2 receiving a vertically polarised radio signal; and

Figure 5 is a graphical representation of the performance of an antenna shown in Figure 2 receiving a horizontally polarised radio signal.

[0010] Referring first to Figure 1, a motor vehicle 10 is there shown having a rear window 12. As in typical rear window constructions, the window panel is made of glass or glass/plastic laminate formed in a conventional manner to include conductive elements such as the rear defogger grid 14. For example, a known heater grid construction is made on the window panel by silk screen painting with a silver ceramic paint before heating the panel to about 593°C to 649°C (1100°F to 1200°F) and forming it to the desired shape before tempering. The silver ceramic paint includes about 95% silver with organic carrier, for example, pine oil, and about 5% glass frit. Heating of the painted panel drives off the organic material, sinters the silver and fuses the glass frit that melts at about 427°C to 482°C (800°F to 900°F). The grid may also be used as an antenna as will be described in greater detail.

[0011] Of course, other processes and constructions can be used to embed or otherwise mount an antenna, for example FM antenna 16, to a concealing panel such as window glass or other dielectric panel. Likewise, similar processes and constructions can be employed to form antennas designed and constructed according to the present invention, for example, as remote keyless entry antennas as shown in 18 for the remote keyless entry system 19 shown in Figure 1, or as the antenna at 20 for the cellular telephone system 21 as shown in Figure 1.

[0012] Although the invention is not limited to these

particular embodiments, the combination of antennas shown in Figure 1 provides an optimum location and advantageous packaging of antennas for a plurality of communication systems. The antennas of the present

5 invention can fit within the perimeter of contemporary window openings along with other screen printed objects such as the heater grid, and provide a particularly useful combination of communication antennas for motor vehicles without obscuring visibility or occupying 10 large conductive surfaces as with previous slot antennas.

[0013] As shown in Figure 2, a model of the antenna 18 shown in Figure 1 is embodied by a ground plane formed from a quarter inch wide strip 23 of copper foil

15 tape with adhesive, for example, a 3M electrical tape about .005 centimetre (.002 inch) thick cut and soldered at the corners to form the shapes shown in the drawing, rather than the wide surface area of conductive material previously employed to form the ground plane of a slot antenna. Nevertheless, other forms of conductors, such as the silver ceramic material used for defroster grid discussed above, can be used to form the ground plane of the antenna for the present invention. The illustrated embodiment aptly demonstrates the effectiveness of

20 antennas constructed according to the present invention.

[0014] Antenna 18 with a substantially reduced ground plane was found to require a substantially shorter slot length 22, and thus a shorter overall length, of 25 one third of the desired wavelength of 315 megahertz, or only about 13.062 inches (33.2 cm) long. In contrast, the length of a slot one half wavelength long at 315 megahertz is 18.75 inches (47.6 cm). As a result, the slot length is substantially less than a half wavelength which

30 is ordinarily expected in a slot antenna. Moreover, the overall area occupied by the antenna is substantially smaller than previously known slot antennas. The width 24 of the slot is determined by conventional standards and practice from known texts, for example, a numerical length to width ratio. In the preferred embodiment, the spacing of 1.125 inches (2.8 cm) between the upper and lower strips matches the spacing existing between the defroster grid lines. Although such spacing is greater than needed for the desired bandwidth reception, it is

35 well above the minimum of about 1/4 inch (.6 cm) required for reception within the RKE radio frequency range.

[0015] The impedance of the antenna is adjusted as 40 with slot antennas by changing the location of the terminals 26 and 28. For example, the terminal 26 formed by centre conductor of a coaxial cable 32 and the terminal 28 formed by the sheath of the coaxial cable 32 the opposite side of the slot, are positioned a distance 30, for example, 1.2 inches (3 cm), from the edge of the slot

45 depending upon the impedance adjustment needed to match the input impedance of the signal transmission line. Moreover, the terminals 26 and 28 are moved together from the edge of the slot for mechanical conven-

ience without adjusting the relative positions between the terminals 26 and 28.

[0016] As just described, the antenna 18 is readily adapted for reception of a predetermined range of frequencies with a sufficient gain to avoid the need for high gain amplification of the signal through an amplifier before reaching the remote keyless entry system 19. In particular, a system operating at a frequency on the order of 315 megahertz is compared with respect to the 0db reference of a dipole antenna in Figures 4 and 5. The data illustrated was obtained by rotating an automobile on a turntable while subjecting the installed antenna panel to a radio signal source generating a polarised signal. At the coordinate position designated FRONT, the front of the car faces the signal source, while the RIGHT SIDE 90° coordinate position refers to a turntable position at which the right side of the vehicle faces the signal source. The 0db level of a dipole antenna rotated on the turntable is shown at 60 while the curve 62 demonstrates performance of the antenna 18 installed in a rear light on a 1992 Mercury Sable in response to a vertically polarised source signal. Similarly, the curve 64 illustrates the 0db level of a dipole antenna response, and the curve 66 illustrates the relative performance of the antenna 18 in response to a horizontally polarised source signal.

[0017] The test data was accumulated and plotted as shown in Figures 4 and 5. The figures represent an area mean of -7.9 db in Figure 4 and an area mean of -11.9 db in Figure 5, with a minimum-to-maximum ratio in Figure 4 of 27.3 db and a minimum-to-maximum ratio of 21 db in Figure 5.

Nevertheless, an antenna according to the present invention may also be employed with remote amplifiers mounted close to the antenna or amplified receivers mounted elsewhere in the vehicle.

[0018] Additional performance for an antenna supported on a nonconductive panel such as a vehicle rear window has also been obtained by adding height to the slot. In addition, the improvement in gain provided by this adjustment is combined with an improvement in the antenna's bandwidth when a second element similar to the antenna 18 is added in parallel to form the antenna 20. As best shown in Figure 3, the ground plane of antenna 20 is formed by a series of conductive loops. The ground plane comprises a conductive strip 43 forming an antenna for reception of radio signals on the order of 855 megahertz, and preferably in the range of 820-895 megahertz. The quarter inch (0.635 cm) copper tape conductor is aligned so that an upper slot having a width of .625 inches and a lower slot having a width of .875 inches is formed with a slot length of 5.00 inches. As with the antenna 18 described above, a cable conductor 52 includes a centre conductor coupled to the upper tape strip at terminal 46 and the intermediate tape strip at a terminal 48, while a grounded shield of cable conductor 52 forms a terminal 50 on the lower strip of the conductive tape.

[0019] The terminals 46, 48 and 50 are located at a distance 1.0 inch (2.5 cm) from the end of the slot in this configuration to provide an impedance matching characteristic that permitted a gain 2 db greater than an antenna having only the lower one of the loops having a slot length of 5.00 inches. Of course as discussed above, different positions of the terminals may be used to affect the impedance represented by the antenna structure. The differing height of the antenna loops in a series of overlapping loops is determined to obtain additional gain and bandwidth improvements. Further improvements may be obtained by stacking additional elements dimensioned according to the performance desired. For example, the antenna 20 installed on the 1992 Mercury Sable had a lower loop width of .875 inches (2.2 cm) matching the heater grid spacing as discussed previously, but having a narrower upper loop with a width of .625 inches (1.6 cm) to raise the frequency of the bandwidth received by the antenna. The stacked arrangement of antenna 20 provides a 2db improvement over an antenna including only the lower loop alone and designed in accordance with the present invention.

## 25 Claims

1. A slot antenna having a slot in a reduced ground plane for a motor vehicle insulating panel comprising:  
30 a conductive strip or tape (23,43) narrow in relation to the width of the slot, formed in a loop on the insulating panel (12), said loop forming the slot having a length (22,44) corresponding to a fraction of a predetermined wavelength, said reduced ground plane consisting of said strip formed in a loop peripherally defining the slot, wherein said fraction is smaller than the half wavelength of an expanded ground plane slot antenna (18,20), said loop is of rectangular form and wherein non-common conductor terminals (26,28,46,48,50) are aligned across the slot on its length sides.
2. An antenna as claimed in claim 1, wherein said antenna comprises a stack of a plurality of loops.  
45
3. An antenna as claimed in claim 2, wherein said loops overlap.
4. An antenna as claimed in claim 1, wherein said antenna is coupled to a receiver by a coaxial cable.  
50
5. An antenna as claimed in claim 4, wherein said receiver is part of a remote keyless entry system or cellular telephone.  
55
6. An antenna as claimed in any one of the preceding claims, wherein said conductive loop is formed on a window glass of the motor vehicle.

7. A motor vehicle window imprinted with a conductive grid for electric window defrosting and a slot antenna, as claimed in any one of the preceding claims, imprinted upon the window.

8. An antenna as claimed in claim 7, wherein said predetermined signal frequency is the operating frequency of a remote keyless entry system.

9. An antenna as claimed in claim 7, wherein said predetermined signal frequency is the operating frequency of a cellular telephone.

5

8. Eine Antenne nach Anspruch 7, worin diese vorherbestimmte Signalfrequenz die Betriebsfrequenz eines ferngesteuerten, schlüssellosen Eingangssystems ist.

9. Eine Antenne nach Anspruch 7, worin diese vorherbestimmte Signalfrequenz die Betriebsfrequenz eines Funktelefons ist.

10

**Patentansprüche**

1. Eine Schlitzantenne für eine isolierende Tafel eines Kraftfahrzeugs, die eine verminderte Grundfläche besitzt, und die umfaßt:  
einen leitfähigen Streifen oder ein leitfähiges Band (23, 43), das im Verhältnis zur Weite des Schlitzes schmal ist, und in einer Schleife auf der isolierenden Tafel (12) geformt ist, wobei diese Schleife den Schlitz bildet, der entsprechend einem Bruchteil einer vorherbestimmten Wellenlänge eine Länge (22, 24) hat; und wobei diese verminderte Grundfläche aus diesem in einer Schleife geformten Streifen besteht, der den Schlitz peripherisch beschreibt; worin dieser Bruchteil kleiner als die halbe Wellenlänge einer Schlitzantenne mit ausgedehnter Grundfläche (18, 20) ist, und diese Schleife von rechteckiger Form ist, und worin unübliche, leitende Endableitungen (26, 28, 46, 48, 50) über den Schlitz hinweg an dessen langen Seiten angeordnet sind.

2. Eine Antenne nach Anspruch 1, worin diese Antenne einen Stapel aus einer Mehrzahl von Schleifen umfaßt.

3. Eine Antenne nach Anspruch 2, worin diese Schleifen überlappen.

4. Eine Antenne nach Anspruch 1, worin diese Antenne durch ein Koaxial-Kabel mit einem Empfänger verbunden ist.

5. Eine Antenne nach Anspruch 4, worin dieser Empfänger Teil eines ferngesteuerten, schlüssellosen Eingangssystems oder eines Funktelefons ist.

6. Eine Antenne nach einem der vorangehenden Ansprüche, worin diese leitfähige Schleife auf dem Fensterglas eines Kraftfahrzeugs geformt ist.

7. Ein Fenster für ein Kraftfahrzeug mit einem aufgedruckten, leitfähigen Gitter zur elektrischen Fensterenteisung, und einer Schlitzantenne nach einem der vorangehenden Ansprüche, die auf das
